

# Understanding SHAMap

**Valentin Balaschenko, Ripple**

XRPL Core Dev Bootcamp 2025

# Core Ledger Team @ Ripple

- ▶ Low-level protocols, high-performance code
- ▶ Personal focus: memory + throughput scalability
- ▶ We're hiring! Engineers welcome
  - ▶ Staff Software Engineer -> <https://ripple.com/careers/all-jobs/job/6437475/>
  - ▶ Senior Software Engineer -> <https://ripple.com/careers/all-jobs/job/6437475/>

# Agenda

- ▶ What is SHAMap?
- ▶ Why SHAMap matters
- ▶ Data Structure Fundamentals
- ▶ Nodes and Hashing
- ▶ Mutability & Snapshots
- ▶ Traversal & Iteration
- ▶ Synchronization & Proofs
- ▶ Storage, Caching, and Thread Safety
- ▶ Q&A

## SHAMap in One Sentence

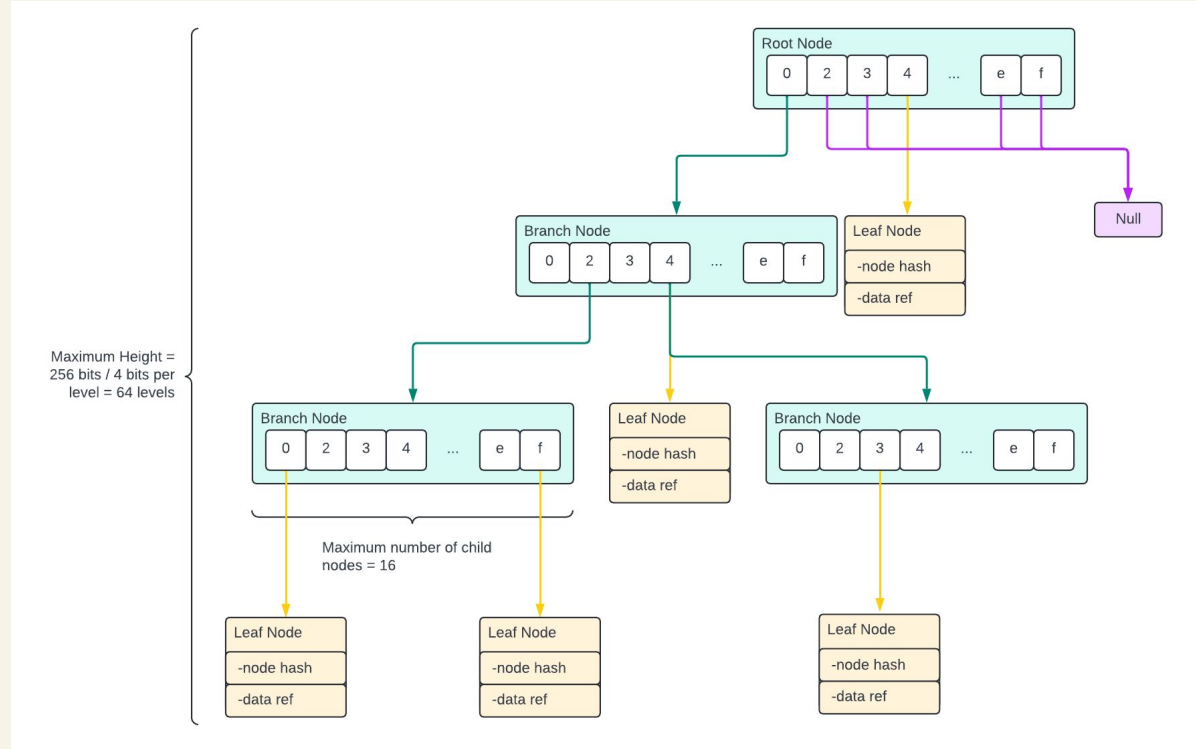

- ▶ A hybrid of Merkle tree and radix trie used to store transactions or ledger state

TODO: remind Merkle and Radix tree/trie structure

## Role of SHAMap in XRPL

- ▶ Backbone of ledger structure
- ▶ Used to store:
  - ▶ Ledger State
  - ▶ Transactions

# High-Level Diagram

## Why Merkle Tree + Patricia Trie?

- ▶ Efficient comparison:  $O(1)$  with hashes
- ▶ Cryptographic integrity
- ▶ Ordered key space

## Uniform Leaf Type

- ▶ SHAMap is homogeneous: leaves are of one type per map
- ▶ State map vs. Tx map

## Types of SHAMap Nodes

- ▶ SHAMapTreeNode (base)
- ▶ SHAMapInnerNode
- ▶ SHAMapLeafNode (+ subclasses)

# SHAMapInnerNode Overview

- ▶ Up to 16 children
- ▶ Bitset + hashes
- ▶ Holds no data
- ▶ FullBelow optimization

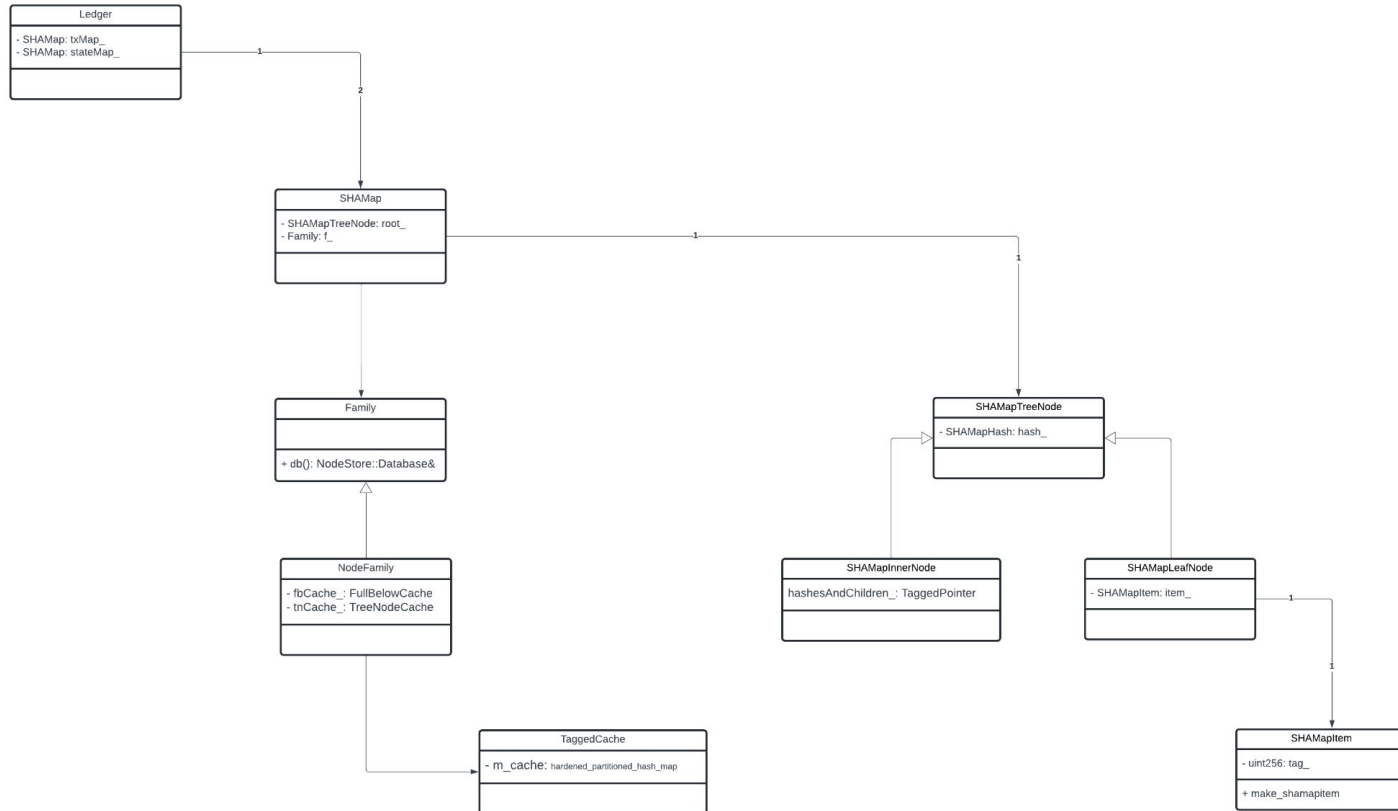

## SHAMapLeafNode Overview

- ▶ Holds SHAMapItem
- ▶ Can be account state, tx, or tx+meta
- ▶ Immutable once inserted

# SHAMapItem

- ▶ tag
- ▶ size
- ▶ raw data
- ▶ intrusive\_ptr based

# Class diagram

# Hashing: The Foundation

- ▶ Each node stores a hash
- ▶ Inner = hash of children
- ▶ Leaf = hash of content

## Hash Update Logic

- ▶ `updateHash()` on leaves: compute hash
- ▶ Inner node: recompute after all children are updated

## SHAMapHash Type

- ▶ Custom hash type for storage
- ▶ Used pervasively across nodes

## Use Cases for Hashes

- ▶ Fast comparison
- ▶ Merkle proofs
- ▶ Data integrity in DB serialization

## Copy-On-Write Model

- ▶ Nodes shareable via `shared_ptr`
- ▶ Modified via clone (copy-on-write)
- ▶ Each SHAMap has a ``cowid``

## Mutability & Snapshots

- ▶ Immutable: for validation/sync
- ▶ Mutable: for building ledgers
- ▶ Snapshots: efficient cloning

# Traversal

- ▶ visitNodes: DFS traversal
- ▶ visitLeaves: filter + callback

## Iteration via `const_iterator`

- ▶ Ordered iteration
- ▶ STL-style API: ``begin()`, `end()`, `lower_bound()``

## walkMap vs walkMapParallel

- ▶ walkMap: missing node detection
- ▶ walkMapParallel: multithreaded sync

## Syncing – getMissingNodes

- ▶ Traverses tree
- ▶ Uses deferred async reads
- ▶ Marks fullBelow on success

## Proof Paths

- ▶ ``getProofPath()`` builds Merkle path
- ▶ ``verifyProofPath()`` checks it
- ▶ Used for light clients

# Canonicalization

- ▶ Ensures one node per hash
- ▶ Avoids duplicates in memory

## Node Identification (SHAMapNodeID)

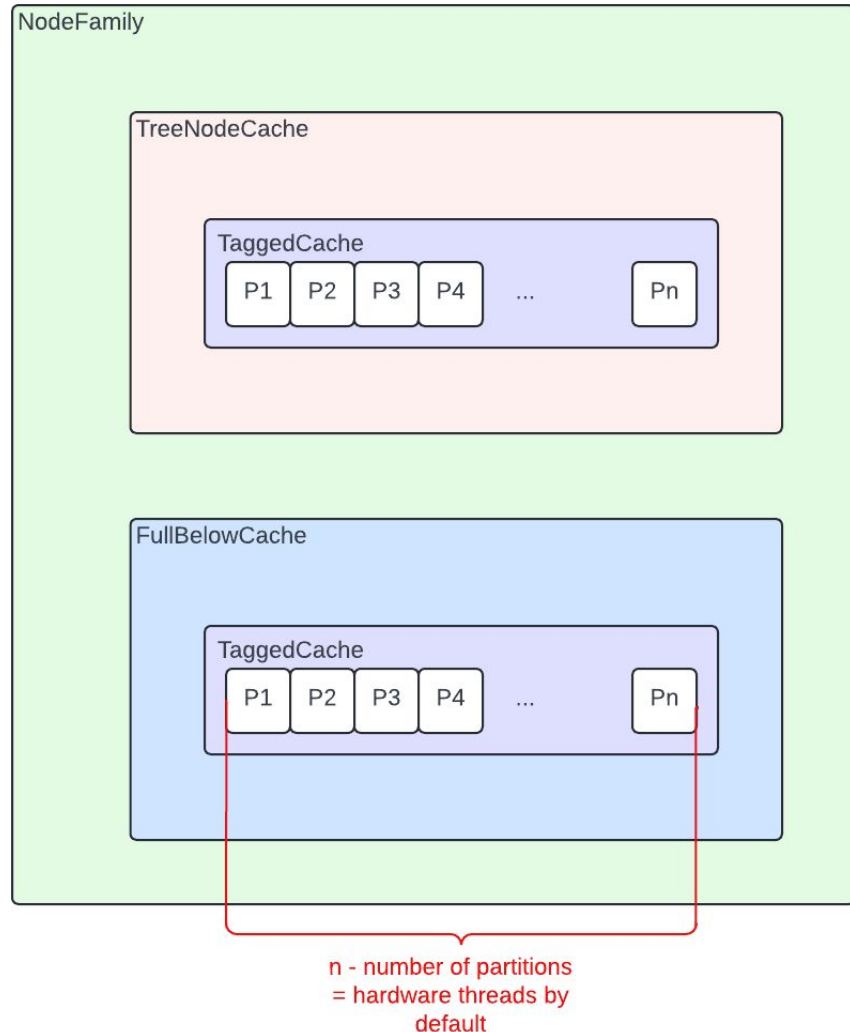

- ▶ Encodes depth + path as uint256
- ▶ Methods: ``getChildNodeID``, ``createID``, etc.

## Inner Node Serialization

- ▶ Full format: all 16 branches
- ▶ Compressed: skip empty branches
- ▶ Chosen automatically

# Caching Architecture

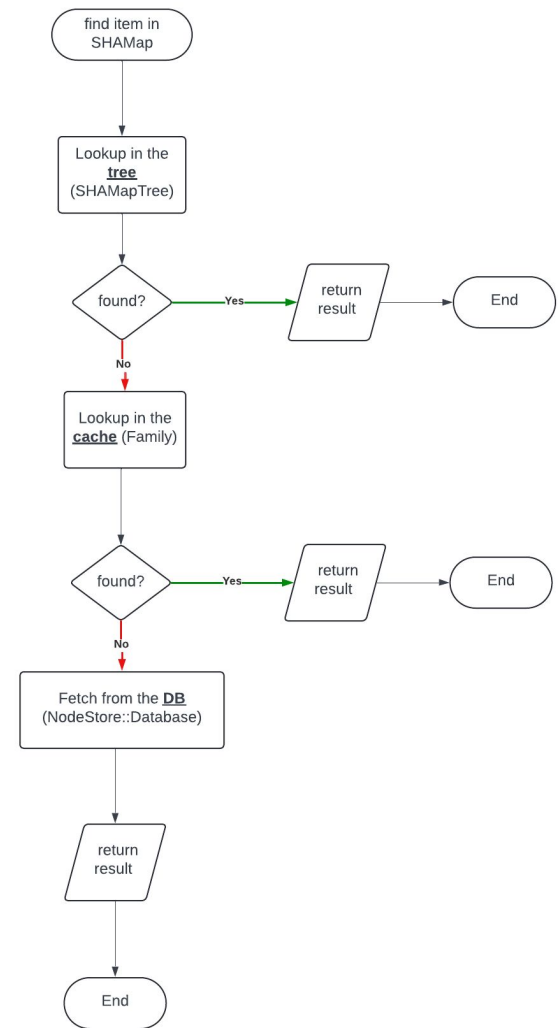

- ▶ TreeNodeCache (hash-indexed)
- ▶ FullBelowCache (fully synced subtrees)
- ▶ Family abstraction (cache+DB mgmt)

# Thread Safety Mechanisms

- ▶ Atomic access in SHAMapInnerNode
- ▶ canonicalize() logic
- ▶ Cache-level synchronization

# SHAMap as a gateway

## Design Summary

- ▶ Immutable-by-default
- ▶ Radix-16 + Merkle
- ▶ Fast sync, proof, comparison

## What's Next?

- ▶ Memory footprint optimisations
- ▶ Transactions throughput optimisations

# Thank you!

▶ Questions?

▶ Exercise (TODO)
